(Twice Amended) In the ink-jet recording head 10 thus constituted, since the

B<sub>3</sub>  
piezoelectric element 19 extends toward the nozzle plate 15 when a voltage is applied to the electrode forming materials 20 and 22 of the piezoelectric element 19, the elastic plate 13 is displaced, and a volume of the pressure generating chamber 12 is compressed. Hence, for example, it is possible to remove a voltage in a state where a bias voltage of about 30V is applied in advance and to make the piezoelectric element 19 shrink, thus causing the ink to flow from the reservoir 17 through the ink supply port 16 into the pressure generating chamber 12. And thereafter, by applying a voltage, the piezoelectric element 19 is extended, the pressure generating chamber 12 is shrunk by the elastic plate 13, and ink droplets are ejected from the ejection port 14.

(Twice Amended) As described above, ink-repellent films denoted by the codes C to F,

B<sub>4</sub>  
the hydration degree is restrained in a range of 0.2 or lower, and the relative polymerization degree is also restrained in a range of 0.2 or lower. It is understood that the ink repellency of the ink-repellent film can be improved by restraining the hydration degree and the relative polymerization degree of the ink-repellent film to be relatively low in such a manner.

B<sub>5</sub>  
In the apparatus thus constituted, the ink-repellent films 25a made of the fluoro carbon resin in the ejection ports 14 can be removed as below. Specifically, the process gas 68 is introduced between the high-frequency electrode 63 and the grounding electrode 66. As shown

B5  
concl. in Fig. 6, the process gas 68 is converted into plasma by the generated gaseous discharges 67. In this embodiment, the process gas 68 is converted into plasma under the atmospheric pressure. Therefore, since an expensive vacuum apparatus is not required for converting the process gas 68 into plasma, the cost can be reduced to be inexpensive. Moreover, evacuation treatment for evacuating a region where the process gas 68 is converted into plasma is not required. Therefore, time required for removing the ink-repellent films 25a can be shortened.

B6 Fig. 8 is an explanatory view showing an in-ejection-port ink-repellent film removing apparatus 80 of the embodiment 3. In this embodiment, the case is shown, where the flourocarbon resin 25a of the ejection ports 14 are removed by ultraviolet rays 81. As shown in Fig. 8, in this embodiment, a chamber 82 disposing the nozzle plate 15 therein is provided. An ultraviolet radiation lamp 83 as ultraviolet radiating means is provided in an upper portion of the chamber 82, and the ultraviolet rays 81 can be radiated downward from the ultraviolet radiation lamp 83. As shown in Fig. 8, the nozzle plate 15 is disposed in a lower portion in the chamber 82. Moreover, in this embodiment, a vacuum pump 84 as pressure reducing means is connected to the chamber 82, and the inside of the chamber 82 is maintained at a pressure nearly vacuum by the vacuum pump 84. Thus, the ultraviolet rays 81 radiated downward from the ultraviolet radiation lamp 83 in the chamber 82 can irradiate the ink-repellent films 25a in the ejection ports 14 without great diffusion or scattering. Since the ink-repellent films 25a in the ejection ports 14 are decomposed by the ultraviolet rays 81, the ink-repellent films 25a can be removed from the ejection ports 14 by irradiating the ultraviolet rays 81. Moreover, the ultraviolet rays 81 have

B<sub>6</sub>  
concl.  
properties that they become attenuated immediately after being reflected. Therefore, the situation can be prevented, where the ultraviolet rays 81 incident onto the ink-repellent films 25a are reflected and incident onto the ink-repellent films 25 of the ejection surfaces 15a. Hence, the ink-repellent films 25a in the ejection ports 14 can be removed without affecting the ink-repellent films 25 on the peripheries of the ejection ports 14. As such ultraviolet rays, the one having a wavelength of 380 nm or shorter can be preferably used, and the one having a wavelength of 200 nm or shorter can be more preferably used. Moreover, in the case where the ink-repellent films 25a in the ejection ports 14 are removed by the ultraviolet rays 81 when the ink-repellent films 25, each having a film thickness of 0.2  $\mu\text{m}$ , are formed, it takes about 10 to 30 minutes for that process.
